Immigration and trade: the case study of Veneto region in Italy

Version: 08.02.2017

Riccardo Fiorentini and Alina Verashchagina^{1 2}

University of Verona

Abstract: This paper investigates the relation between immigration and trade by focusing on Veneto region in Italy. The reference period is 2008-2015, interfering with the economic crisis, thus the results obtained can be time specific. The presence of immigrants in Veneto was constantly on the rise, also during the crisis, although at a lower pace compared to pre-crisis years. The question is which role could this play in ascertaining the stability, if not expansion, of trade relations between the region and the countries of immigrants' origin. The estimates of gravity model suggest a non-linear relationship between the number of immigrants and total *exports from (imports to) the host-province to (from) the country of origin*, the type of this relation moreover differs by sector of origin of trade. Higher presence of immigrants can potentially induce shifts in the structure of local economy, especially if it is highly dependent on international trade like in the case of Veneto.

Keywords: Immigration, Exports, Imports, Gravity model, Dose-response function.

Introduction

Migration is known to stimulate bilateral trade between countries involved³ (see e.g. Egger et al. 2012, Genc et al. 2012). Bratti et al. (2014) who used the Italian province data, suggest that the effect is mainly pro-import. At the same time Aleksynska and Perri (2014) point out that the outcome depends on the composition of immigrants stocks. Immigrants in business network occupations are the one who intensify exports.

This paper aims to enhance our understanding of the impact of immigration by looking at one of the Italian regions, Veneto. It is one of the most dynamic regions in Italy experiencing a huge inflow of immigrants over the recent decades (ORI 2015). Our main enquiry here is whether the latter translates in higher international trade volumes. We start by looking at the aggregate trade volumes between the single provinces and the countries of origin of immigrants and then propose a disaggregate analysis by looking at different sectors. This way we are going to check whether there is a differential impact of immigration on trade originating from different sectors of economy. The composition of trade volumes may in fact be changing over time with the number of immigrants alongside the characteristics of both sending and accepting countries. The key question is whether immigration is able to change the structure of the host economy or does it reinforce already existing specialization.

Several steps are being followed in order to verify the existence of causal relation between immigration and trade flows and define the type of this relation.

First, we estimate the so-called gravity model, where the number of immigrants enters alongside to other characteristics of both provinces and countries of origin of migration which can potentially impact on bilateral trade (exports/imports).

Then we exploit the methodology proposed by Imbens (2000) which consists in estimating the dose-response function. The latter allows to determine the causal relation between the number of immigrants (our treatment variable) at each level of immigration flows and exports/imports (our outcome variables). The information obtained this way can be instrumental to setting up migration quotas.

The reference period for this paper is 2008-2015 which overlaps with the economic crisis, thus the conclusions obtained might be time specific. The study can be thought as an extension to a

³ Different channels are at work the most studied being networking and preference effects (see e.g. Felbermayr and Toubal 2012).

comprehensive analysis for Italy implemented by Bratti et al. (2014)⁴. The scope of our paper is to highlight the most recent developments, but also check which way the crisis might influence the much-debated relationship between immigration and trade.

In what follows we first provide a brief survey of the literature on the impact of migration on trade. In section two, we explain why the focus was put on Veneto and present the most recent trends regarding migration and international trade in the region. The data and methodology used in the empirical part of the paper are discussed in section three. Section four presents the main findings. We end up with some concluding remarks.

1. Literature review and the hypothesis to be tested

There was an increasing number of studies looking at migration and trade. The first attempts to test the causal relation were made for the US (Gould 1994). Since then numerous case studies appeared, including Girma and Yu (2002) for the UK, Bruder (2004) for Germany, Briant et al. (2014) for France, Artar-Tur et al. (2012) for Italy, Spain, and Portugal, Bratti et al. (2014) for Italy. Most of existing studies converge in that there is a positive impact of migration on trade. These findings have been also confirmed by cross-country analysis, including Egger et al. (2012), based on the OECD data, and Genc et al. (2011), a meta-analysis relying on 48 previous studies.

Despite there seems to be no doubt that migration stimulates bilateral trade, the consensus has not been reached as to the magnitude and stability of this effect, which is partly explained by methodological differences. Some of the recent studies point out that the relationship is not of the log-linear type (see e.g. Egger et al. 2011, Requena and Serrano 2013), in particular the effect is the largest at small levels of migration, whereas there is a certain point of saturation beyond which the pro-trade effect becomes almost negligible.

Besides using more sophisticated methodologies, additional insights have been gained from more detailed data on both trade volumes and immigrants. Herander and Saaverda (2005) distinguished between in-state and out-state immigrants in the US, suggesting that network effects are enhanced by proximity. This is in line with the more traditional gravity models used in the literature where the distance between countries has always been one of the key ingredients (De Benedictis and Taglioni 2012). Artal-Tur et al. (2003) also point out the importance of using small

⁴ Their trade flows data spans from 2003 to 2009, whereas immigration stocks data covers the period 2002-2008.

geographical units, having proved that export enhancing effect is localized within the hosting province, i.e. it would not manifest if immigrants live outside the given province⁵.

In their recent study Aleksynska and Peri (2014) outline the importance of the composition of immigrants stocks, after incorporating into the analysis the occupational data for immigrants. They find that each business network immigrant generates over ten times the value of trade than a non-business network immigrant does.

Trade volumes data has also been subject to scrutiny. Egger and Wolfmayr (2014) point out that the estimates of gravity models often differ substantially once trade volumes data is taken from different supranational sources. Here we opt for the use of regional statistics data on exports (imports) from (to) Veneto (made up of 7 rather homogeneous provinces), which can be a disadvantage in that the obtained results would be region specific. On the other side, the data on trade volumes originating from different sectors (and subsectors) is expected to provide new insights. Few studies only has taken this perspective by looking at single sectors, see e.g. Ottaviano et al. (2015) referring to the UK service sector⁶.

We hypothesize that the composition of products involved in bilateral trade could be changing over time with the number of immigrants. The main question is whether immigration is able to change the structure of the local economy or does it reinforce already existing specialization. The outcome might depend on the composition of immigrant inflows, on how well they get assimilated, and on how far they can go in establishing their own business⁷. It would also depend on the characteristics of both sending and accepting countries like the ones entering the traditional gravity equation⁸.

⁵ In testing the importance of network effects Rauch (1999) moreover distinguished between homogeneous (those possessing a reference price) and differentiated products.

⁶ De Arcangelis et al. (2015a) looked at the manufacturing sector in Italy by associating the share of migrant workers with broader indicators of firm performance such as Sales/Workers and Production/Workers. A significant effect was found for the relatively low-tech sectors.

⁷ Bratti et al. (2016) highlight the role of diasporas and ethnic firms for the development of trade relations between countries.

⁸ $F = G \frac{m_1 * m_2}{r^2}$, according to which the two objects attract each other with a force that is directly proportional to the product of their masses and inversely proportional to the square of the distance between them (G is the gravitational constant). By analogy, higher "economic mass" (proxied by VA/GDP per capita of accepting province and the sending country) is expected to stimulate bilateral trade, whereas longer distance between countries can be an impediment to trade.

2. The case study of Veneto region

2.1. Migration profile

Veneto is among the regions attracting the highest shares of immigrants coming to Italy. At the beginning of 2015, the total number of immigrants was around 5 mln. people, with more than half of them concentrated in Lombardy (23%), Lazio (12.7%), Emilia-Romagna(10.7%) and Veneto (10.2%) (ORM 2015). One out of ten person residing in Veneto nowadays has foreign origins.

Figure 1. Geographical areas of origin for foreigners living in Veneto

Source: own elaboration using ISTAT (foreign residence) data referring to 01.01.2015.

More than one third of immigrants come from Central and Eastern Europe, the second largest share (30%) corresponds to Africa, followed by Asia (27%), and only a bit more than 5 percent are from America (Fig. 1). The main countries of origin of Extra-Communitarian (Non-EU) immigrants are Morocco, China, Albania, and Moldova (see Tab. A1 in the Appendix)⁹.

Figure 2 maps the distribution of residence permits issued to non-EU citizens over the earliest and the latest years covered in this study. Veneto was and remains among the dark areas on the map, suggesting that the region continues attracting immigrants in large numbers¹⁰. The highest levels have been observed in the case of Rome, Naples and Milan metropolitan areas¹¹.

⁹ Romania holding the lead position is not included in the list, since after accession to the EU back in 2007 the permit is no longer necessary for Romanian citizens staying in Italy.

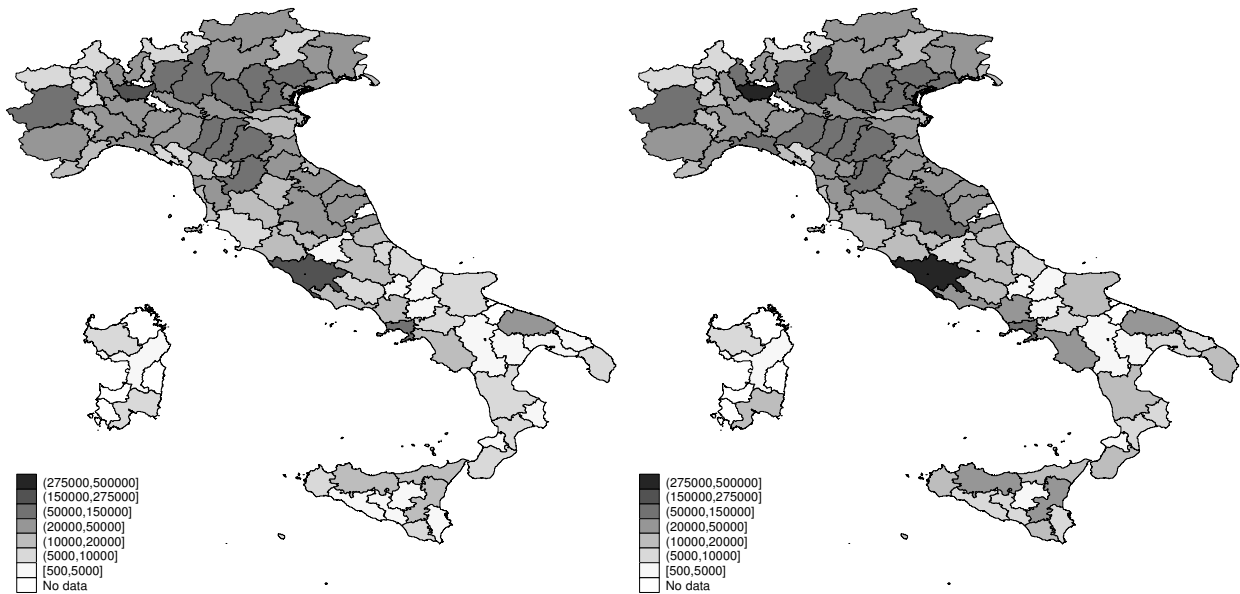

¹⁰ This may seem in contrast to findings emerging from ORI (2015) reporting the recent reduction in foreign resident population in Vicenza and Treviso. The discrepancies are due to the fact that we use information on residence permits which applies to non-EU citizens only. It appears to be less affected by acquisitions of Italian citizenship (which peaked in 2013-2014) compared to the data on foreign resident population (for more details see Data section).

¹¹ Rome in Milan in particular have seen the largest increase in the number of new entries per year (plus almost 150,000 and 200,000 respectively), reaching the highest mark of 470,601 in the case of Milan (01.01.2015).

2.2. The structure of local economy and international trade

In terms of economic dimension, Veneto is the third region in Italy with a 9.0% share of Italian GPD in 2015 after Lombardia (21.05%) and Lazio (11.12%). However, the economic structure of Veneto is different with a greater role of manufacturing which accounted for 23.12% of the regional VA in 2014. In comparison, in the same year the VA weight of manufacturing in Lombardia and Lazio were equal to 19.80% and 5.66% (ISTAT, National Accounting Database)¹². It is also worthwhile noting that manufacturing in Veneto absorbs a share of total regional employment (32%) which is greater than its share of VA¹³. The core role of the industrial sector in the regional economy also explains while despite the service sector growth in the last decades, a large part of it also serves the needs of manufacturing. In so far as specialization is concerned, in the last decade there was a shift towards more technology-intensive productions and a simultaneous reduction in the share of traditional goods (from 9.4% in 2005 down to 6.4% in 2011) with recent interesting steps in the direction of the development of a low emission sustainable economy¹⁴.

¹² http://dati.istat.it/Index.aspx?DataSetCode=DCCN_PILPRODT

¹³ Unioncamere Veneto (2016a) p. 33, Table 2.1

¹⁴ Unioncamere Veneto (2016a) pp. 166-76

The analyses of the spatial distribution of economic activity reveals a clustering of firms in the central part of the region with two provinces¹⁵, Vicenza and Treviso, which produce almost half of the regional VA in manufacturing (27.71% and 20.92%). Noteworthy is the case of Vicenza which is one of the most industrialized area in Italy with a share of manufacturing of 35.49% , a figure more than twice greater than the Italian average (15.51%).

Veneto is very open to international trade. The region is running a persistent trade surplus and is the second Italian exporting region supplying 14% of total Italy’s export (Unioncamere Veneto, 2016b). In 2015, export accounted for 10% of the region’s GDP. Figure 2 shows the negative impact of the international crisis of 2009 on foreign trade of Veneto which nonetheless returned on the previous upward trend in 2010. At the NUTS 3 (province) level, Vicenza alone generates 28.53%of the regional export, followed by Treviso (20.88%) and Verona (17.86%).

Figure 3. International trade of Veneto in the period 2001-2015 (millions of euros)

Source: ISTAT COEWEB database

In 2015, EU absorbed 58.17% of regional export remaining the most important market for Veneto. Among individual countries, Germany, France, USA, UK, Spain and Switzerland have been the main destinations for goods produced in Veneto. In so far as emerging countries are concerned, China is the most important trade partner, being the second exporter to Veneto and the tenth importer (Unioncamere Veneto 2016a: Table. 2.3). The position of China as the second supplier of imported goods reflects the internationalization of the regional value chain, particularly in the

¹⁵ Provinces in Veneto region are Belluno, Padova, Treviso, Venezia, Verona and Vicenza.

textile and fashion sectors. In the wake of the economic crisis which hit the main trade partners too, emphasis has been made on expanding trade relations with emerging markets. Among the latter, in the last five years Mexico, Arab Emirates, Saudi Arabia and Hong Kong have been the most dynamic countries of destination of products from Veneto (Unioncamere Veneto, 2016b).

The composition of exports is dominated by mechanical and fashion industries (Unioncamere Veneto 2016a: Table. 2.2). BBF¹⁶ products are an important part of the output from Veneto and represent about one third of exports from the region. They have been especially welcomed in emerging countries like Russia, Brazil, China, and India.

Table A.2 in the Appendix provides information on export and import volumes towards top ten countries of origin of immigrants, as identified in Tab. A1. It gives some evidence on the relation between immigration and trade. In particular, most of these countries have seen considerable increase in trade with Italy. The biggest increase in exports was observed towards Albania, Bangladesh, Serbia, India, China, and Nigeria, whereas imports increased most from Bangladesh, Albania, Serbia, Moldavia, China and India. In terms of levels China and India lead both of the lists.

In what follows we are going to study empirically the existing relation between immigration and trade. The section to come will present the data and methodology we are going to use for this purpose.

3. Data and methodology

3.1. Data

Our unit of analysis is a couple 'Italian province-Country of origin of immigration', the later being also *a destination/origin for exports from/imports to* a given province. The data on trade, immigrants and other country/province characteristics derives from different sources.

The key variables we use are *export/import volumes* (dependent) and the *number of residence permits* (explanatory) as an indicator of immigrants' presence. Residence permits are issued to non-EU citizens, thus we do not take in account immigrants coming from Old and New Member States (including Romania and Bulgaria) . An alternative could be using the number of

¹⁶ 'Bello e Ben Fatto' (BBF, *eng.* Beautiful and Well-Made,) indicates Made-in-Italy medium-high level goods from old traditions which are innovative in terms of design and state-of-the-art technology. BBF are produced according to high quality and professional standards.

foreign resident population¹⁷. But since no homogeneous time series is available for periods before and after the last census implemented in 2011, we opt to use residence permits. Our main focus is on internationalization and diversification of trade partners, which implies going beyond the boundaries of the EU, thus the concept of permits of stay could be more appropriate.

Total *exports/imports* are used first over the period 2008-2015. Then we distinguish between exports originating from different sectors as of ATECO (Classification of Economic Activity) 2007¹⁸ at 1-digit level (see Table A3 in the Appendix), complementing the analysis with the estimates by different subsectors of manufacturing¹⁹. The data on trade volumes comes from regional statistics for Veneto²⁰ while the source of information on permits is ISTAT (the National Statistical Institute)²¹.

In addition we use the *great circle distance* between the main city in the Italian province and the capital city in the country of origin of immigrants in order to assess its weight on bilateral trade (for more details see Tab. A3 in the Appendix). Other characteristics include the total value added²² for accepting province and the GDP per capita²³ for the country of origin of immigrants.

3.2. Methodology

Our basic model derives from the literature on gravity models in international trade (see e.g. De Benedictis and Taglioni 2011). We first estimate the following type of equation for *total exports/total imports* by province versus the country of origin of immigration:

$$\ln(\text{Exp}_{ijt}+1)=\text{Immigr}_{ijt-1} +\text{Immigr}_{ijt-1}^2 + \ln(\text{Distance}_{ij})+\ln(\text{VA}_{it-2})+\ln(\text{GDPpc}_{ppjt})+X_{ijt}+\lambda_{ijt}+\varepsilon_{ijt} \quad (1)$$

$$\ln(\text{Imp}_{ijt}+1)=\text{Immigr}_{ijt-1} +\text{Immigr}_{ijt-1}^2 + \ln(\text{Distance}_{ij})+\ln(\text{VA}_{it-2})+\ln(\text{GDPpc}_{ppjt})+X_{ijt}+\lambda_{ijt}+\varepsilon_{ijt} \quad (2)$$

¹⁷ This would include immigrants coming from other EU Member States [ISTAT: "Foreign resident population is represented by individuals who do not have Italian citizenship having usual residence in Italy. It is calculated for each municipality on December 31st of each year that follows the population Census, adding to the foreign population enumerated by the census the foreign population inflows and outflows recorded during each calendar year"]

¹⁸ A National version of the European nomenclature NACE Rev.2.

¹⁹ Data on exports/imports by pseudo-subsectors of manufacturing (ATECO 2007, 2 digits) comes from ISTAT, COEWEB database [https://www.coeweb.istat.it/predefinite/tutto_paese_merce.asp?livello=ATE07_L2&riga=MERCE&territorio=S&AG=S]

²⁰ http://statistica.regione.veneto.it/banche_dati_economia_commercio_estero.jsp

²¹ We are grateful to colleagues from ISTAT, in particular Dott.ssa Cinzia Conti, for providing us with this data. The list of 41 countries includes: AL, BA, HR, MK, MD, RU, TR, UA, CH, DZ, EG, MA, TN, BF, CI, GH, NG, SN, ER, ET, MU, SO, CM, CG, IR, LB, SY, BD, IN, PK, LK, CN, PH, US, AR, BR, CO, CU, DO, EC, PE.

²² <http://statistica.regione.veneto.it/servlet/scaricoXls?downfile=ContoEc5.xls>

²³ <http://data.worldbank.org/indicator/NY.GDP.PCAP.CD/countries>

where $\text{Exp}_{ijt} / \text{Imp}_{ijt}$ stands for Exports /Imports from 'province i to country j '/ 'country j to province i ' in time t , Immigr_{ijt-1} is a measure of immigrants stock from country j in province i at time $t-1$ (measured by the number of permits issued and still valid on the 1 of January in year t), VA_{it-2} is the value added reported for a given province in year $t-2$ ²⁴, GDPpc_pp_{jt} is the GDP per capita for country j in year t , X_{ijt} is a vector of other characteristics of countries/provinces or province-country pairs, λ_{ijt} is a vector of fixed effects and ε_{ijt} is an error term. We further repeat the estimation by considering exports/imports from specific sectors ($\text{Exp}_{ijt_s} / \text{Imp}_{ijt_s}$) as well as subsectors of manufacturing ($\text{Exp}_{ijt_ss} / \text{Imp}_{ijt_ss}$) reported in Tab. A3 of the Appendix.

Note that the log-linear transformation suggests the following interpretation of the obtained coefficients for the number of immigrants. A one unit increase in *Immigr* yields an increase in export volumes by a multiple of e^β . Given the *Immigr* defined as the number of permits issued by country divided by 1000²⁵, the final interpretation would be that 1000 increase in the number of immigrants would increase exports by a multiple of e^β .

Then we proceed by tackling the number of immigrants as a form of treatment variable (having in mind immigration quotas as a possible policy instrument). The estimation of average treatment effect requires adjustment for differences in pre-treatment variables, and to this end we use the generalized propensity score (GPS).²⁶ This way we solve the problem of drawing causal inferences (Imbens 2000). GPS is then used to estimate the average dose-response function which associates an average potential outcome (exports/imports) to a certain level of treatment T (number of immigrants). The regression model is the following²⁷, and it is just analogous for imports:

$$\ln(\text{Exp}_{ijt}+1) = \text{Immigr}_{ijt-1} + \text{Immigr}_{ijt-1}^2 + \text{GPS} + \text{GPS}^2 + \text{Immigr}_{ijt-1} * \text{GPS} \quad (3)$$

The treatment effect function is also reported which represents the first derivative of the dose-response function. It shows the effect of the marginal increase in the number of immigrants on bilateral trade flows.

²⁴ The two-year lag was dictated by the availability of data.

²⁵ This was done to leverage the values for the number of immigrants and export volumes given that the latter enters the specification in logarithmic format.

²⁶ GPS has the meaning of conditional probability of receiving certain level of treatment given pre-treatment variables. Once we have the estimate of GPS, instead of having to adjust for all pre-treatment variables, it is sufficient to adjust for GPS.

²⁷ The estimates of this model do not have direct interpretation. They are used to construct the dose-response function as in Figure A.1 of the Appendix.

4. Main findings

The estimates of gravity model reported in Table A.5 of the Appendix confirm our expectations in that there is a positive relation between the number of immigrants present in the territory and exports towards the country of their origin. At the same time, a negative relation is observed between the number of immigrants squared and exports, suggesting a non-linear relationship between the key variables of interest.

Estimates by sector suggest that immigration tends to stimulate exports from A-agriculture, B-mining, C-manufacturing, E-water supply and waste management, as well as V-sector producing other goods; the remaining sectors including D-electricity and gas supply, J-information and communication, M-professional, scientific and technical activities, R-arts, sports and entertainment, as well as S-sector producing other services do not respond to an increase in the number of immigrants.

Since manufacturing has always been and remains the key sector for the Veneto region we went deeper by looking at different subsectors of manufacturing. The estimates reported in Tab. A6 of the Appendix suggest that the inflow of immigrants is associated to higher export volumes of food and drinks (CA), textile, leather goods and accessories (CB), chemical products (CE), metal products and equipment (CH), computer and electronic equipment (CI), machines and equipment (CK) and transport means (CL); less so for products of wood (CC), rubber and plastic goods (CG), electrical devices (CJ); and is practically irrelevant for exports of oil and petroleum products, as well as pharmaceutical and medical products. In the case of imports, the picture is quite similar in terms of significance by subsectors except for the case of computer, electronic and optical devices for which imports are not sensible to the presence of immigrants (differently from exports).

The use of logarithmic transformation in our specification does not allow direct interpretation of the coefficients obtained. But after some manipulations (explained in the methodology section) we obtain that one hundred increase in the number of immigrants from certain country is expected to increase exports towards that country by 2.8%. The elasticity of total imports with respect to the number of immigrants is higher than that of exports. One hundred increase in the number of immigrants from certain country is expected to increase imports from that country by 8%. The estimates appear to be slightly higher compared to the findings from a meta-study by Genc et al. (2011) reporting 1-2% increase in exports associated to an increase in the number of immigrants by 10%.

Higher distance between countries is an obstacle, as the coefficient for geographical distance is negative and significant for total exports as well as for 6 out of 8 sectors considered; it weights also on (total) imports, although this effect is less significant down to inexistent in more than half of the sectors considered.

Provinces generating higher value added tend to both export and import more. This does not hold true only for M-professional, scientific and technical activities in the case of imports.

The export /import flows are larger towards/from countries characterized by higher GDP per capita, again with few exceptions observed at sector level. These regards water supply and waste management (E) for exports.

In an attempt to test the type of relationship between immigration and trade we estimate the dose-response function for both exports and imports. The graphical presentation of the dose-response function in Figure A1 confirms the non-linear relationship which moreover varies by sector. As can be seen from Figure A2.1, the maximum effect on exports is achieved in Manufacturing, at relatively low levels of immigration flow, around 4 thousand people. The same holds true for imports as can be grasped from Figure A2.2. Worth noting that the pro-trade effect gets weaker for imports to manufacturing at higher levels of immigration, whereas it survives for exports from manufacturing.

We went further by looking at subsectors of manufacturing. Most of them are able to take advantage from increasing the inflow of immigrants by exporting more. In the case of textile and clothing, but also wood and paper products, pharmaceutical products and transport means, going beyond 15 thousand new entrants from a single country would allow surpassing the previously identified local maximum of pro-trade effect.

The existence of several maxima may not be very intuitive but is a result which is not rare in the literature on the link between migration and trade since the seminal paper by Gould (1994)²⁸. Our tentative explanation is that immigrants who come first are probably the most open-minded and ready to take risks, which can be helpful in establishing trade relations between countries. They also facilitate trade conveying information about the formal and not-formal aspects of the economy of their originating countries which helps reducing transaction costs in the trade relationship with the immigrants' destination countries (Parsons and Winters, 2014: pp. 19-21). The second wave of immigrants is in part represented by their family members who are not expected to contribute in developing trade relations in the same extent. Higher order maxima may be the result of network effects which gain importance in business relations as long as there is space for the joint

²⁸ See also Herander and Saavedra (2005), Parsons and Winters (2014), Wagner et al. (2002).

use and accumulation of capital, as well as the result of learning by doing (Rauch, 1999). Positive experience of creating trade-partnerships may stimulate further increase in trade between countries.

Concluding remarks

The paper aims to enhance our understanding of how the increase in the number of immigrants might affect trade relations between sending and hosting countries. The focus here was on one of the Italian regions, Veneto, which has been and remains among the main attractors for foreigners coming to Italy. The share of foreign-born population living in Veneto nowadays has surpassed 10%. This has raised concerns regarding the impact of immigration on the structure of local economy.

We address these issue by first estimating the standard type gravity model, for both total exports/total imports from/to the single provinces of Veneto region to/from the countries of origin of immigrants. Then we perform the estimates separately by sectors of economy in order to understand whether they react differently to the inflow of immigrants. The study period spreads from 2008 to 2015.

Our empirical estimates confirm that immigration has a potential to increase bilateral trade by affecting both exports and imports. The elasticity of aggregate imports with respect to the number of immigrants is nevertheless higher for imports. A closer look suggests that the effect on imports is mainly concentrated in manufacturing sector, whereas that on exports is more evenly distributed among several sectors. In particular, agriculture, mining, manufacturing, water supply and wastes management, as well as sectors producing other goods are the ones which react positively by exporting more in response to increase in the number of immigrants. This could mean that a further increase in the number of immigrants might induce shifts in the structure of local economy of Veneto region which is highly dependent on international trade.

Future developments can be affected by policy actions such as setting up migration quotas. The estimates of the dose-response function can be instrumental in this respect by suggesting the levels of immigration allowing to achieve the maximum effect on trade.

Table A3. Variables definition

Variable	Description
Exp_{ijt}/Imp_{ijt}	Total exports /imports from province <i>i</i> to country <i>j</i> in year <i>t</i>
Exp_{ijt_s}/Imp_{ijt_s}	Exports /Imports originating from sector <i>s</i> in province <i>i</i> towards country <i>j</i> in year <i>t</i> . Sectors are defined on the basis of 1-digit ATECO (Classification of Economic Activity) 2007 and include in particular: A -agriculture, forestry and fishing; B -mining; C -manufacturing, D -electricity and gas supply; E -water supply and wastes management; J -information and communication; M -professional, scientific and technical activities; R -arts, sports and entertainment; S -other services; V -other goods.
$Exp_{ijt_ss}/Imp_{ijt_ss}$	Exports /Imports originating from a specific subsector of manufacturing <i>ss</i> in province <i>i</i> towards country <i>j</i> in year <i>t</i> . So-called pseudo-subsectors are defined on the basis of 2-digit ATECO Classification 2007 and include in particular: CA -food products, drinks and tobacco; CB - textiles, clothing, leather goods and accessories; CC - wood and products of wood; paper and products of print; CD - oil and petroleum products; CE - chemical products and substances; CF - pharmaceutical, chemical, medical and botanical products; CG - products of rubber/plastic/minerals; CH - metals/metal products, excluding machines and equipment; CI - computer, electronic and optical devices; CJ - electrical devices; CK - machines and equipment; CL - transport means; CM - products of other manufacturing activities.
$Immigr_{ijt-1}$	The number of immigrants (in thousands), measured by the number of permits (<i>ital. permesso di soggiorno</i>) issued in province <i>i</i> and still valid on the 1st of January in year <i>t</i> , by country of origin <i>j</i> (citizenship).
$Distance_{ij}$	The <i>great circle distance</i> between the main city in the Italian province and the capital in the country of origin of migration. It is calculated in the following way. We first transform the latitudes and the longitudes of the two cities, respectively (<i>a1, b1</i>) and (<i>a2, b2</i>) as of www.latlong.net , into radians, multiplying by ($\pi/180$). The following formula is then used to calculate the distance between the two cities: Distance [1,2] = $\arccos [\sin a1*\sin a2+\cos a1*\cos a2*\cos(b1-b2)]*z$, where $z=6371\text{km}$ (radius of Earth).
VA_{it-2}	The value added created by province in year <i>t-2</i> (2-year lagged value).
$GDP_{pc_{jt}}$	GDP per capita for country <i>j</i> in year <i>t</i> (PPP, current international US\$).
